

**AMENDMENT TO THE SPECIFICATION**

On pages 23-24, please amend paragraph [077] as follows:

[077] The hash and route (H&R) block 335 makes all of the routing decisions for ingress packets from the high-speed receiver ports 330-332 by calculating, for each packet, an output virtual channel (OVC) which is used for internal switching on the multiprocessor device 300. The packets are then sent to either the packet manager input (PMI) 322 or to one of the transmit ports 350-352. The H&R module 335 is located in each of the three high-speed receiver ports 330-332. As a packet 301 enters the receiver port (e.g., 330), it is decoded and control information is extracted by the receiver interface or decoder 333. The H&R module 335 calculates the routing result by using this control information along with the packet data and several programmable tables in the H&R module 335. Routing information is encoded in the form of a switch or output virtual channel (OVC) which is used by the on-chip switch 310 to route packets. The OVC describes the destination module, such as the PMI 322 or transmitter ports 350-352, and either the input queue number (IQ) in the case of the PMI or the output channel in the case of the transmitter ports. When targeting the packet manager 320, the output virtual channel corresponds directly to IQs. On the output side, the packet manager 320 maps an OQ into one OVC which always corresponds to a transmitter port. In addition, multiple sources can send packets to a single destination through the switch. If packets from different sources (receivers 330, 331, 332 or PMO 324) are targeted at the same output VC of a transmitter port or the IQ of the PMI 322, the switch 310 will not interleave chunks of packets of different sources in the same VC. Both the packet data and its associated route result are stored in the receiver buffer 338 before the packet is switched to its destination. The H&R module 335 can be implemented by the structures disclosed in copending U.S. patent application entitled "Hash and Route Hardware With Parallel Routing Scheme" by L. Moll, Ser. No. \_\_\_\_\_, filed \_\_\_\_\_, Serial No. 10/684,871, filed 10/14/2003, now U.S. Patent 7,366,092, and assigned to Broadcom Corporation, which is also the assignee of the present application, and is hereby incorporated by reference in its entirety.

On page 37-28, please amend paragraph [077] as follows:

[0117] While multiple individual counter circuits could be used to implement the interrupt and descriptor timers for multiple channels (e.g., 64 virtual channels), such a solution would consume valuable chip area and would increase the system complexity, especially where independent and different time-out settings are required for multiple channels. Accordingly, an exponential channelized timer is advantageously used in connection with multi-channel, multiprocessor applications such as depicted in Figures 3-5 to efficiently provide a programmable timer with individual time-out settings for multiple channels. In a selected embodiment, an exponential channelized timer monitors a selected bit position of a free-running timer and generates a pulse whenever a transition is observed at that bit location. In this embodiment, the time-out values that can be set are exponential values (power of 2), so the exponential channelized timer acts as an interval timer where the timer accuracy goes down as the interval increases. For example, if an exponential channelized timer for a particular channel is programmed to monitor bit location number five of a free running 32-bit counter, then the time-out will be generated within a time interval of  $32(2^5)$  and  $63(2^6-1)$ , reflecting the fact that the free running timer is not reset with each first packet. As will be appreciated, this interval increases exponentially as the monitored bit location register becomes more significant. Therefore, the timer gets less accurate as this value is increased. However, by using multiplexers and control registers for each channel, the exponential timer can be used to generate time-outs for multiple channels without requiring long timer counters for each channel, using only a single free running counter. The timer module 330 can be implemented by the structures disclosed in copending U.S. patent application entitled "Exponential Channelized Timer" by K. Oner, Ser. No. \_\_\_\_\_, filed \_\_\_\_\_, Serial No. 10/684,916, filed 10/14/2003, and assigned to Broadcom Corporation, which is also the assignee of the present application, and is hereby incorporated by reference in its entirety.
